Assignment 11 FAQs

Q1. What is a template in C++?

Ans A template is a feature for writing generic functions or classes that can work with different data types. The compiler generates the required concrete versions when they are used.

Q2 What is the difference between a function template and a class template?

Ans- A function template defines a family of functions, such as generic maximum functions. A class template defines a family of classes, such as a box that stores different types.

Q3- When does the compiler generate a specific template instance?

Ans- A specific instance is generally generated when the program uses the template with particular template arguments. The type must support the operation required by the template.

Q4- What are the main advantages of templates?

Ans- Templates reduce duplicated code and improve reuse across compatible data types. They retain compile time type checking and can provide efficient compiled code.

Qs. ~~What~~ How are templates related to the STL?

Ans- The standard template library uses class templates for containers such as vector, list and stack and function templates for many algorithms. Templates allow these components to work with many types.
