Experiment - 1 FAQs

1. What is Pascal's Triangle ?

Ans: Pascal's Triangle is a triangular arrangement of numbers in which the first and last number of every row are 1. Each inner number is the sum of the two numbers directly above it.

2. Why are nested loops suitable for this program?

Ans: The outer loop controls the rows, while inner loops print spaces and numbers within each row. This makes it easy to repeat the required operations for a changing number of rows.

3 What is the relationship between Pascal's Triangle and binomial coefficients ?

Ans: Each number in row n is a binomial coeffient, written as C(n,r). These coefficients appear in the expansion of (a+b)

4. What features are provided by OOP languages compared with procedural languages ?

Ans: OOP supports classes, objects, encapsulation, inheritance and polymorphism. Procedural programing mainly organizes a program around functions and step-by-step procedures.

5. What is runtime initialization?

Ans: Runtime initialization means assigning a variable it's initial value while the program is running often using user input or a calculated expression. For example, int n; cin >> n; obtains the value at runtime.

6. What is the difference between function definition, function call and function declaration?

Ans: A declaration tells the compiler a function's name, return type and parameters. A definition contains the function body while a call executes the function.
