Assignment 10 FAQs.

Q1. What is an exeption?

Ans An exeption is an abnormal condition that interupts normal program flow such as attempting an invalid operation. C++ uses exception handling to transfer control to code that can handle the problem.

Q2. What is the purpose of a try block?

Ans A try block contains code that may throw an exeption. path. The runtime searches for a matching catch block.

Q4- How is a matching catch block selected?

Ans- The runtime compares the thrown exeption's type with the types accepted by the available catch handlers. A compatible handler is selected, if none exists, the exeption continues propogation.

Q5. What is the advantage of standard exception classes such as runtime-error?

Ans They provide meaningful, structured error information and work with the standard exeption hirarchy. Their what() function can provide a diagnostic message.

Q6. Explain different run-time exeptions like in a C++ program.

Ans Examples are std:: out_of_range for an invalid checked index, std::bad_alloc when memory allocation fails, and std::runtime_error for a runtime failure. Division by zero with built in integers is not automatically a C++ exception, so the program must check and handle it.

Q7 Can we write multiple catch block for one try block?

Ans- Yes, a single try block can be followed by multiple catch blocks for different exception types. Put more specific handlers before general handlers.
