Experiment - 5 FAQs

1. What is function overloading ?
Ans Function overloading means defining multiple functions with the same name but different parameter lists.. The functions can differ in the number types or order of parameters

2 Why is function overloding called compile time polymorphism ?
Ans The compiler selects the appropriate function by examining the arguments in the call. This selection happens at compile time.

3 Can two functions be overloaded only by changing their return types ?
Ans No, The parameters lists must differ, changing only the return type is not enough for overloading. Otherwise a call would not identify which function to use.

4. What information does the compiler use to choose an overloaded function ?
Ans It examines the function name, number and types of arguments and possible type conversion. If no unique best match exists the call is ambiguous and compilation fails.

5. How is function overloading different from function overriding?

Ans Overloading uses the same function name with different parameter lists, usually in the same scope. Overriding redefines a base class, virtual function in a derived class with a matching signature.

6. Explain encapulation and how classes achieve it?

Ans : Encapsulation combines data and related functions in a class. Private data members and public functions help control access to the internal state.
