Experiment - 6 FAQs

1. What is operator overloading
Ans Operator overloading defines how an existing C++ operator behaviour for a user defined type. For example + can be defined to add two complex objects.

2. Which operators were overloaded in this experiment?
Ans The arithmatic operators +, -, * and / were overloaded. They perform addition, subtraction, multiplication and division.

3 Can operator precedence be changed by overloading?
Ans No, Operator overloading can not change an operator's precedence, associativity or number of operands. It only defines the operator's behaviour for suitable user-defined types.

4. What is the advantage of returning a complex object from an overloaded opertor?
Ans The operation can return a new object containing the calculated result without changing the original operands. It

It only defines the operator's behaviour It also allows natural expression such as c1 + c2

5. How is operator overloading different from function overloading?

Ans Function overloading gives the same function name different parameters lists. Operator overloading defines an existing opertor's behaviour for class. or other user-defined types.

6. How does operator overloading improve readbility for complex numbers?

Ans It allows mathematical expressions such as c1+c2 instead of longer calls such as c1.add(c2). This makes the code resemble the mathematical notation.
