Assignment 9 FAQ

Q1. What is run time polymorphism?

Ans Run time polymorphism allows the same interface to produce different behaviour depending on the actual type object type during execution. In C++ it is commonly achieved using inheritance and virtual function.

Q2. What is virtual function?

Ans- A virtual function is a base class member function declared with the virtual keyword. When called through a base class pointer or reference, the appropriate overidden derived class function can run.

Q3. What is dynamic binding?

Ans- Dynamic binding means selecting the function implementation at runtime based on the actual object type. It is the mechanism behind virtual function dispatch.

Q4. What is a pure virtual function?

Ans- A pure virtual function is declared with =0, for example virtual double area()=0; A class containing one is abstract and cannot be initiated directly.

Qs:) Why should a polymorphic base class generally have a virtual destructor?

Ans- A virtual destructor ensures that deleting a derived object through a base class pointer invokes the derived destructor as well as the base destructor. This helps release sources correctly.
